

# Predicting blue crab (*Callinectes sapidus*) fisheries independent survey abundances and commercial landings in Charleston Harbor, South Carolina

28Jan2020 edit: 1

Stephen R. Czwartacki

Michael R. Kendrick

## Abstract

Marked high fluctuations in blue crab (*Callinectes sapidus*) seasonal and annual abundance, and commercial landings are typical, but data from both fisheries independent and dependent surveys have shown declines in populations in recent years in South Carolina. Despite several long-term fisheries independent surveys encountering blue crab, predictive models have not recently been developed in South Carolina to quantify variation in abundance and commercial landings. The goal of this study is to assess the current status of blue crab in SC and explore the potential for developing a more predictive understanding of commercial landings. This goal is met through the following objectives: 1) assess long-term trends in blue crab landings and fisheries-independent abundance, 2) test the applicability of a juvenile index, where juvenile abundance in one year predicts adult abundance in a following year, 3) explore predictive relationships between fisheries-independent abundance and commercial landings. Data from several long-term South Carolina Department of Natural Resources (SCDNR) fisheries independent blue crab surveys were standardized for each of six surveys and commercial landings data were compiled. Analyses testing the application of a juvenile index of abundance show that no juveniles collected in surveys explain variation in annual survey abundances. The Creek Trawl survey was the only survey with significant, but weak, correlative relationships between multiple lagged population structure variables and its own annual abundance. Significant relationships were found with effort-corrected commercial landings predicted by the previous year's abundance of male crabs. This relationship was significant for immature crabs collected in the Harbor Trawl survey, and for mature crabs collected in the Creek Trawl survey. These results suggest effective population sampling, but a potential influence on abundance of blue crab from outside factors such as fishing, habitat or environmental variables.

## Methods

Data were put through a rigorous data wrangling process to standardize each survey relative to its own methods. Fisheries dependent commercial landings and fisheries independent survey abundances were truncated from statewide data to Charleston Harbor watershed data.

Surveys cover a range of habitats.

**Table 1:** Methods - SCDNR fisheries independent survey methodology. This table sums up some of the differences in methodology from each of the survey. I think it covers a range of of different methodology variables (temporal, spatial, gear, standardization, sample numbers, etc.).

Survey	Gear		Sample			Data	
	Gear Method	Gear Type	Sample Area	Sample Interval	Sample Method	N(events)	CPUE Standardization
CRMS							
Creek Trawl	Active	6m Trawl, 2.54cm stretch mesh	Ashley River, Wando River	Monthly, May-Sep	Fixed Stations	1827	Time
Harbor Trawl	Active	4.6m Trawl, 0.6cm D mesh	Ashley River, Charleston Harbor	Monthly	Fixed Stations	2956	Time, Gear
Ashley Fall Potting	Passive	0.6 x 0.6 x 0.46m Pot, 3.8 cm mesh	Ashley River	Monthly, Oct-Nov	Randomized Block w/in a Fixed Station	128	Time
ERS							
SCECAP Tidal Creeks	Active	5m trawl, 1.9cm bar mesh	Charleston Harbor Systemwide	Jun - Aug	Random Stratified	62	Volumetric
SCECAP Open Water	Active	5m trawl, 1.9cm bar mesh	Charleston Harbor Systemwide	Jun - Aug	Random Stratified	92	Volumetric
IFRS							
Trammel Net	Passive	183 x 2.1m trammel net	Charleston Harbor Systemwide	Monthly	Random Stratified	4736	None (Total)

**Table 2:** Lifestage data for blue crab by SCDNR fisheries independent survey. It should be mentioned in the methods what type of lifestage data is available from these surveys. The “legal” category is pretty redundant. “Legal” = “Adult, and”Sublegal” = “Juvenile” + “Subadult”, although at shows the potting survey having some size data and sublegal can be considered a joint variable (juv + subadult).

Survey	Total CPUE	Size			Legal (Size)		Class (Sex/Maturity)			
		Juvenile	Subadult	Adult	Legal	Sublegal	Immature Female	Mature Female	Immature Male	Mature Male

## Objective 1

Assess long-term trends in blue crab landings and fisheries-independent abundance

Figure 1: Objective 1 - Plot represents mean annual time series of (A) total landings in total lbs./yr and (B) mean annual effort-corrected landings (total lbs./pot pulled/yr) for the combined reporting areas of the Charleston Harbor watershed

Fisheries Independent Survey Abundances  
Charleston Harbor (Combined Watersheds)

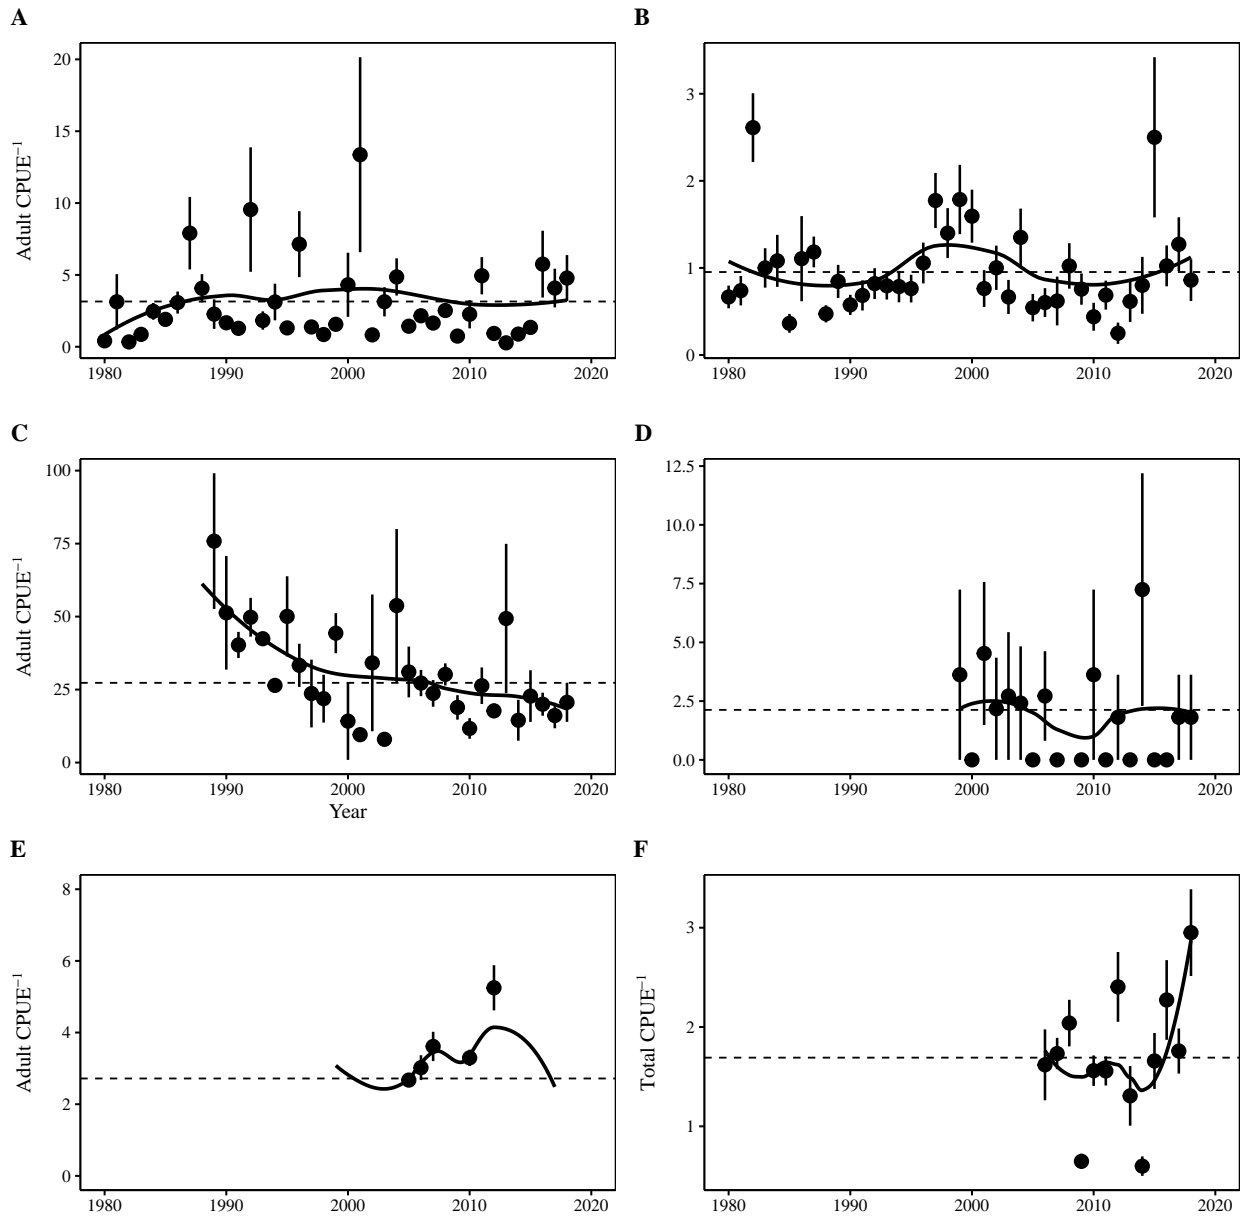

Figure 2: Objective 1 - Plot represents mean annual adult survey abundances of the (A) Harbor Trawl, (B) Creek Trawl, (C) Ashley Potting Survey, (D) SCECAP Open-Water and (E) SCECAP Tidal-Creek surveys, with standard error, long-term mean (dashed) and a LOESS smoothing line (solid). The Tammel Net survey does not have size or sexual maturity data and is represented by total CPUE in this plot.

## Methods

## Discussion

Time series of mean annual commercial landings (fig. 1) and adult abundances from SCDNR fisheries independent surveys (fig. 2) show the high annual variability of blue crab populations. These figures both show crab >126mm, which is the minimum legal limit of blue crab in South Carolina.

The total pounds landed in the combined Charleston Harbor watersheds shows a trending decline from 2003 - 2010, but when these same landings data are corrected for effort in terms of number of pots pulled that trend is not observed. The year 2003 marks the first year of “trip ticket” reporting, in which all commercial blue crab license holders are required to report their catch. This is the same time (>2003) landings data have incorporated data from the Ashley River and Cooper River reporting areas. This could be due to not being actively fished for blue crab, underreported for these reporting areas or included in another reporting area (e.g. a line of crab pots beginning in the Ashley River and continuing into Charleston Harbor where landings are eventually reported). Adult abundances from some surveys (B Creek Trawl, C Ashley Potting and D SCECAP Open-Water) show a slight decline in adult abundance shortly after 2000.

## Objective 2

Test the ability of a juvenile index, where juvenile abundance in one year predicts adult abundance in a following year

**Table 3:** Objective 2 - These are all relevant explanatory variables. Only one survey has explanatory relationships with its own lagged abundances. No juveniles from any survey predict abundances in later years. The relationship between total CPUE and subadults with a 2-yr. may suggest that 1) the survey does not catch juveniles effectively or juveniles are not populating sampled micro-habitats.

Dependent Variable	Explanatory Variable	Summary Statistics		
		p-value	r <sup>2</sup>	Degrees of Freedom
Total CPUE	Subadult (2-yr. lag)	0.001926	0.2432	35
Total CPUE	Mature Male (1-yr. lag)	0.002197	0.2321	36
Total CPUE	Immature Male (2-yr. lag)	0.004023	0.2131	35
Total CPUE	Sublegal (1-yr. lag)	0.004317	0.2102	35
Total CPUE	Total CPUE (2-yr lag)	0.004898	0.2050	35
Total CPUE	Subadult (1-yr. lag)	0.007774	0.1809	36
Total CPUE	Immature Female (2-yr. lag)	0.010380	0.1733	35
Adult CPUE	Mature Male (1-yr. lag)	0.014170	0.1558	36
Total CPUE	Mature Female (2-yr lag)	0.019000	0.1473	35
Total CPUE	Total CPUE (1-yr lag)	0.019060	0.1434	36
Total CPUE	Sublegal (1-yr. lag)	0.025290	0.1314	36
Total CPUE	Mature Male (2-yr. lag)	0.030760	0.1265	35
Total CPUE	Adult (1-yr. lag)	0.031200	0.1225	36
Total CPUE	Legal (1-yr. lag)	0.031200	0.1225	36
Adult CPUE	Mature Female (2-yr lag)	0.036771	0.1187	35
Total CPUE	Immature Male (1-yr. lag)	0.048540	0.1038	36
Total CPUE	Immature Female (1-yr. lag)	0.050070	0.1025	36

Figure 3: Objective 2 - Shows the potential to predict, but poor correlation. Prediction by subadult with a 2-yr lag suggests that either juveniles are underrepresented in sampling, or maybe they do not congregate until this size? THIS PLOT IS NOT NEEDED AND WOULD NEED CLEANUP

## Discussion

OLS regression models using all lifestages from all surveys with a 1- and 2-yr lag to predict all survey's total CPUEs were constructed to find all explanatory relationships. The CRMS Creek Trawl survey is the most consistently responsive of the surveys when used in regression modeling. Fifteen significant relationships exist between total CPUEs from the Creek Trawl survey and several 1- and 2-yr.lagged lifestage variables (Table 3). The CRMS Harbor Trawl had one significant explanatory relationship with subadults from the same survey lagged 1-yr. The Trammel Net survey had one significant explanatory relationship with mature females from the Harbor Trawl lagged 1-yr, which is the highest correlation ( $r^2=0.36$ ) of all the single regression models.

Although there were several significant regression models constructed using fisheries independent survey life stage abundance CPUEs, no relationships correlate strong enough to be effective models. Using OLS single regression modeling, the six SCDNR fisheries independent surveys used to monitor blue crab populations in the Charleston Harbor watershed are ineffective predictors of their own abundance CPUEs. When these single variables were used to populate multiple regression OLS models, the adjusted  $R^2$  values did not improve the correlations. Juvenile variables did not predict mean annual CPUEs.

## Objective 3

Explore predictive relationships between fisheries-independent abundance and commercial landings.

**Table 4:** Objective 3 - All significant relationships of effort corrected Charleston Harbor watershed (Ashley, Cooper and Wando Rivers and Charlesotn Harbor) commercial Landings by lifestage variables from all surveys using OLS regression. Only variables from the Harbor and Creek Trawl surveys were related to these corrected landings. Multiple variables with consistent correlations through both surveys seem to suggest the surveys are effectively measuring the population, but there may be some other driver (habitat, environmental, fishing) outside of stock/population (proper term?) variables that affect blue crab abundance.

Dependent Variable	Explanatory Variable	Summary Statistics			
		p-value	r2	F-statistic	Degrees of Freedom
Harbor Trawl (explanatory variable)					
Mean Landings CPUE	Mature Male (1-yr. lag)	0.007659	0.4330	9.928	13
Mean Landings CPUE	Subadult (1-yr. lag)	0.016680	0.3670	7.538	13
Mean Landings CPUE	Total CPUE (1-yr. lag)	0.027710	0.3208	6.140	13
Creek Trawl (explanatory variable)					
Mean Landings CPUE	Immature Male (1-yr. lag)	0.010420	0.4076	8.946	13
Mean Landings CPUE	Sublegal (1-yr. lag)	0.014850	0.3772	7.875	13
Mean Landings CPUE	Subadult (1-yr. lag)	0.019470	0.3532	7.100	13
Mean Landings CPUE	Total CPUE (1-yr. lag)	0.023880	0.3346	6.538	13
Mean Landings CPUE	Juvenile (1-yr. lag)	0.030140	0.3129	5.921	13
Mean Landings CPUE	Immature Female (1-yr. lag)	0.033210	0.3038	5.672	13

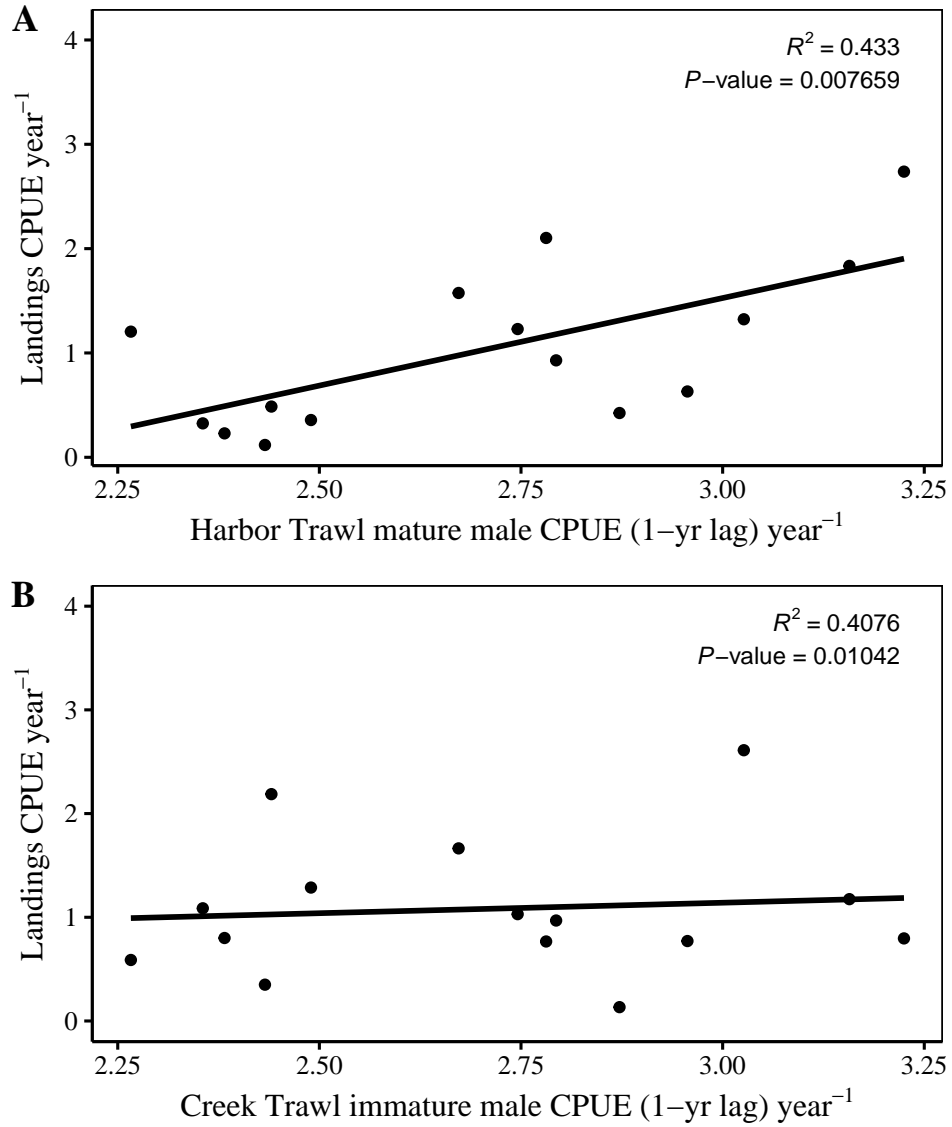

Figure 4: Ordinary Least Squares regression plots of select significant explanatory relationships using lagged variables to Charleston Harbor watershed Landings CPUEs. Mean annual landings CPUE by Harbor Trawl mature males with a 1-yr lag (A), and mean annual landings CPUE by Creek Trawl immature males CPUE with a 1-yr. lag (B). Because the multiple regression relationships do not have as strong a correlation as some of the single, and are more illogical, I don't think the table with multiple regression models is needed since there is no improvement in correlation.

Figure 5: Objective 3 - This plot shows no model improvement if Total CPUEs are added together into a multiple regression model. The adj  $R^2$  is not an improvement over the  $R^2$  of the individual variables (See Table 4)

**Table 5:** Objective 3 - This table shows the results of a dredge function run on the highest correlated variables (Figure 4), the total CPUEs (1-yr. lag) for the Harbor and Creek Trawl surveys (univariate corrs found Table 4). The multivariate model's  $R^2_{adj}$  was lower than the univariate models. The multivariate and univariate models were scored using AICc for small samples. A  $\Delta < 2.0$  from another model's  $\Delta$  means the dredge sees no statistical difference outside of chance between the compared models. Mean annual population structure variables (Harbor Trawl mature males 1-yr lag, Creek Trawl immature males 1-yr lag) are statistically better models than mean annual total CPUE according to the dredge.

		lagged 1-yr.				df	logLik	AICc	delta	weight

## Discussion

OLS regression models using all lifestages from all surveys with a 1- and 2-yr lag to predict Charleston Harbor watershed (Ashley River, Cooper River, Wando River and Charleston Harbor) landings CPUEs were constructed to find all explanatory relationships. All significant relationships are displayed in the following tables. The CRMS Creek Trawl is the most consistently responsive of the surveys when used in regression modeling. Nine significant relationships exist between mean annual Landings CPUE and several 1- and 2-yr.lagged lifestage variables from the CRMS Harbor and Creek Trawl surveys (Table 4). The CRMS Harbor Trawl survey's mature males 1-yr. lag and the CRMS Creek Trawl survey's immature male 1-yr. lag are the only variables with a coefficient of determination (r-squared)  $> 0.40$ . Multiple regression OLS models populated with these variables did not improve correlation.

Only two fisheries independent life stage abundance CPUEs have significant relationships with total landings (not effort corrected). The effects from these models have very small explanatory power over total landings. It should be mentioned that  $>2003$  is when data from all 4 reporting areas (Ashley, Cooper, Wando Rivers and Charleston Harbor) and the effort-correction (pots pulled) begin.
